

The late decline reverses when neighborhood weights are held fixed

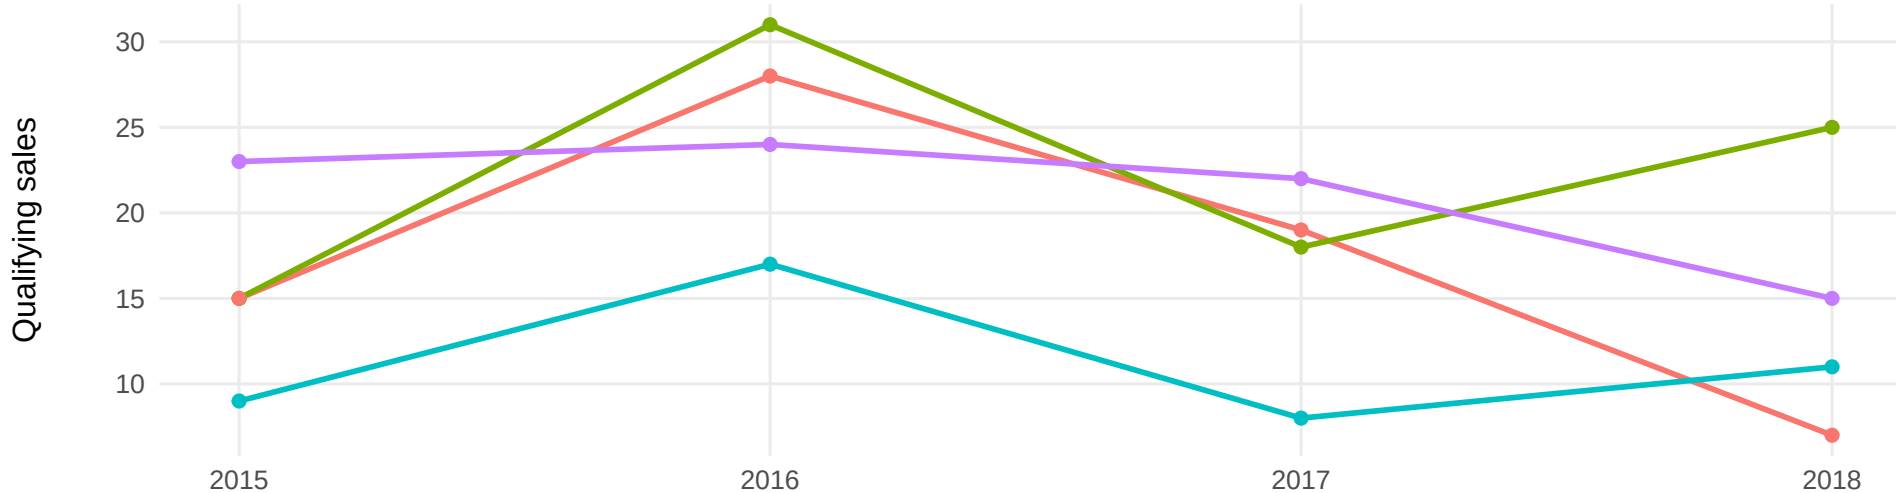

Treated group, quarter-mile sample; all 29 treated sites observed in each year

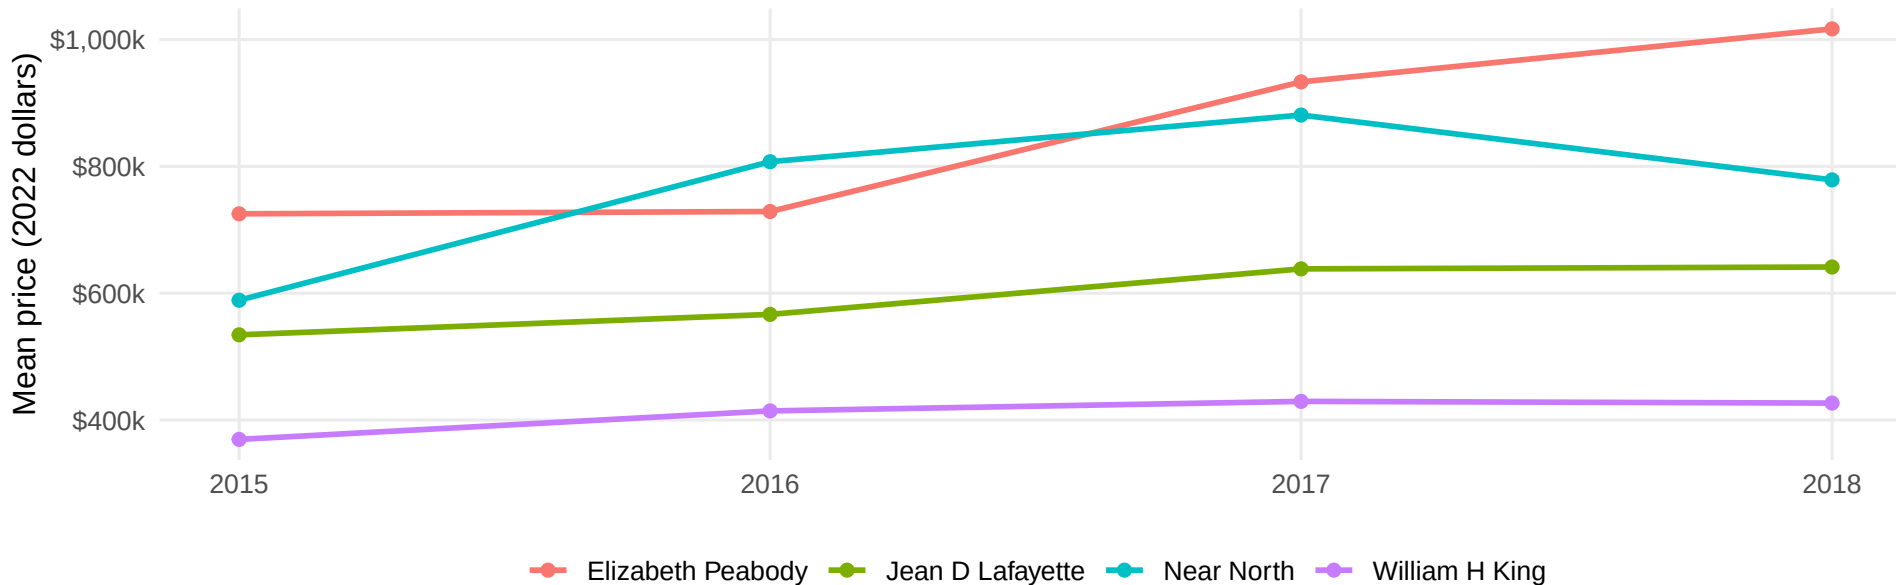

Fixed weights use each site's share of treated sales in 2016; within-site transaction means still vary.
This isolates changing neighborhood shares. It is not a repeat-sales or constant-property price index.

Which neighborhoods contribute to the decline?

Fewer sales in expensive school neighborhoods

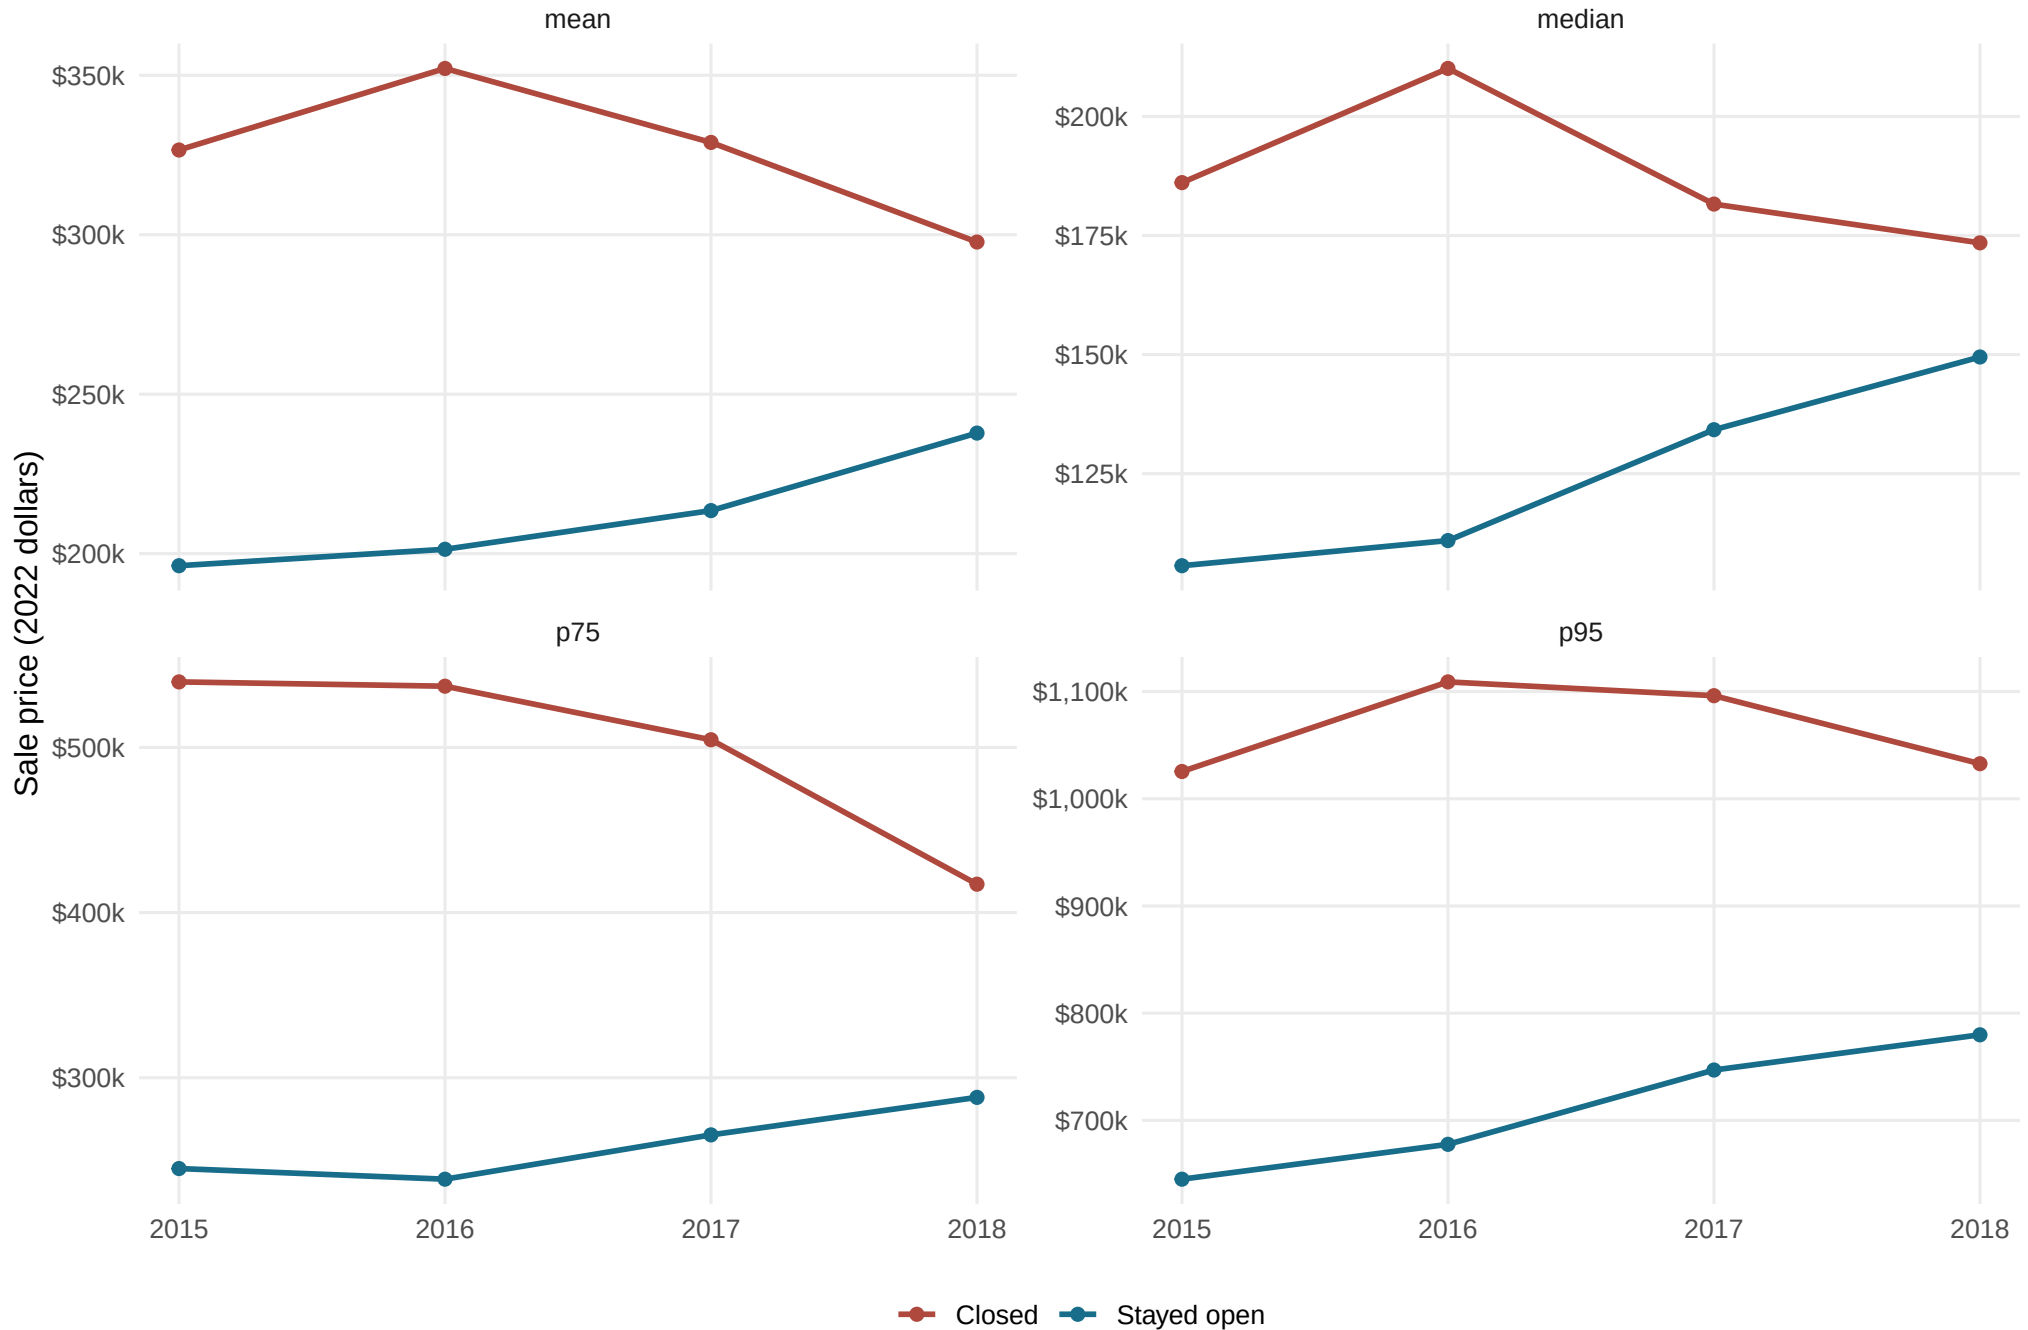

Their average prices do not fall together

Four largest negative contributions to the pooled treated mean, 2016–2018.
Contribution changes include both the site's prices and its share of all treated sales; quarter-mile sample.

The decline is strongest below the very top of the distribution

Quarter-mile descriptive sample; percentiles calculated within each group and year

The treated median is nearly unchanged from 2017 to 2018, while the mean continues falling. These statistics describe changing transactions, not the appreciation of the same homes.
